*= parameters recorded in the field during the first day of sampling using a field multi-probe (Hydrolab Quanta, Hydrolab Corporation®, Texas, USA); discharge was measured by the salt dilution method (Hongve, 1987); suspended solids were evaluated by filtering 500 mL of water through 0.45- μm -membrane MFS filters and drying at 105°C for 30 min. Nutrients, silica, and ions in 1 L of stream water were measured in the laboratory according to Standard Methods (APHA, 2005). Standing crop of algae was estimated as chlorophyll *a* concentration by scraping, at each site and date, an area of 9 cm² from three stones selected randomly from the channel. Chlorophyll *a* was extracted with 90% acetone and the concentration was read at 665 and 750 nm according to Standard Methods (APHA, 2005).

Tab. S2. Physico-chemical properties and concentrations of the 11 pollutants tested in *Diamesa cinerella* (Dc) and *Diamesa zernyi* (Dz). In the Vermigliana stream pollutants were measured in winter, in Presena in summer. Risk level was performed by S. Villa S. and V. Di Nica (Lencioni *et al.*, 2017).
